

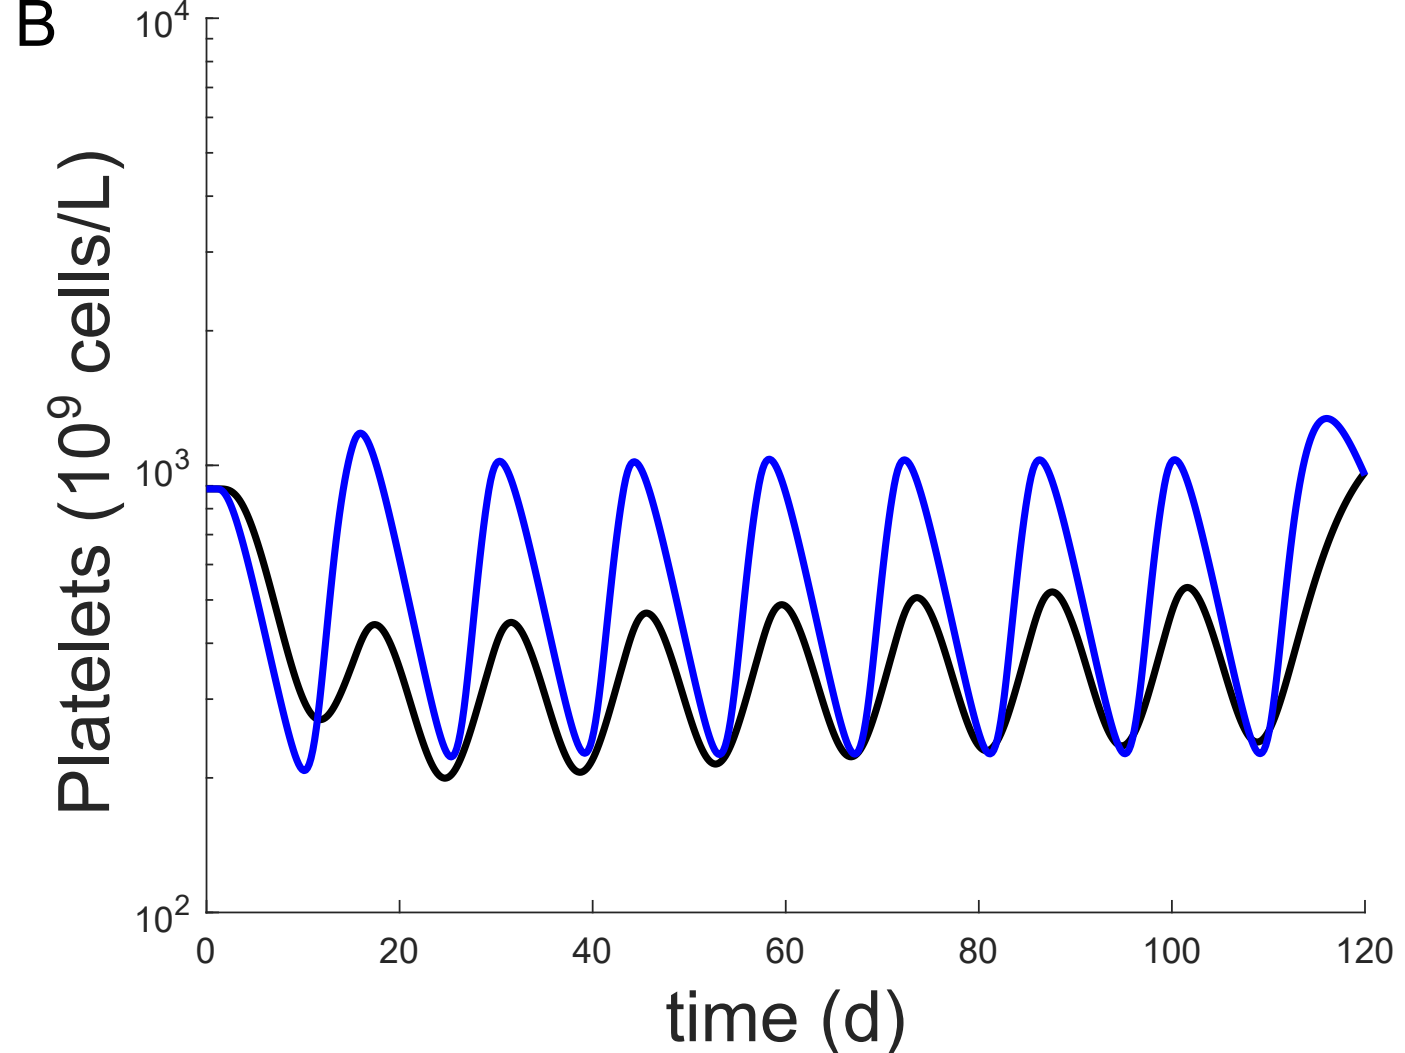

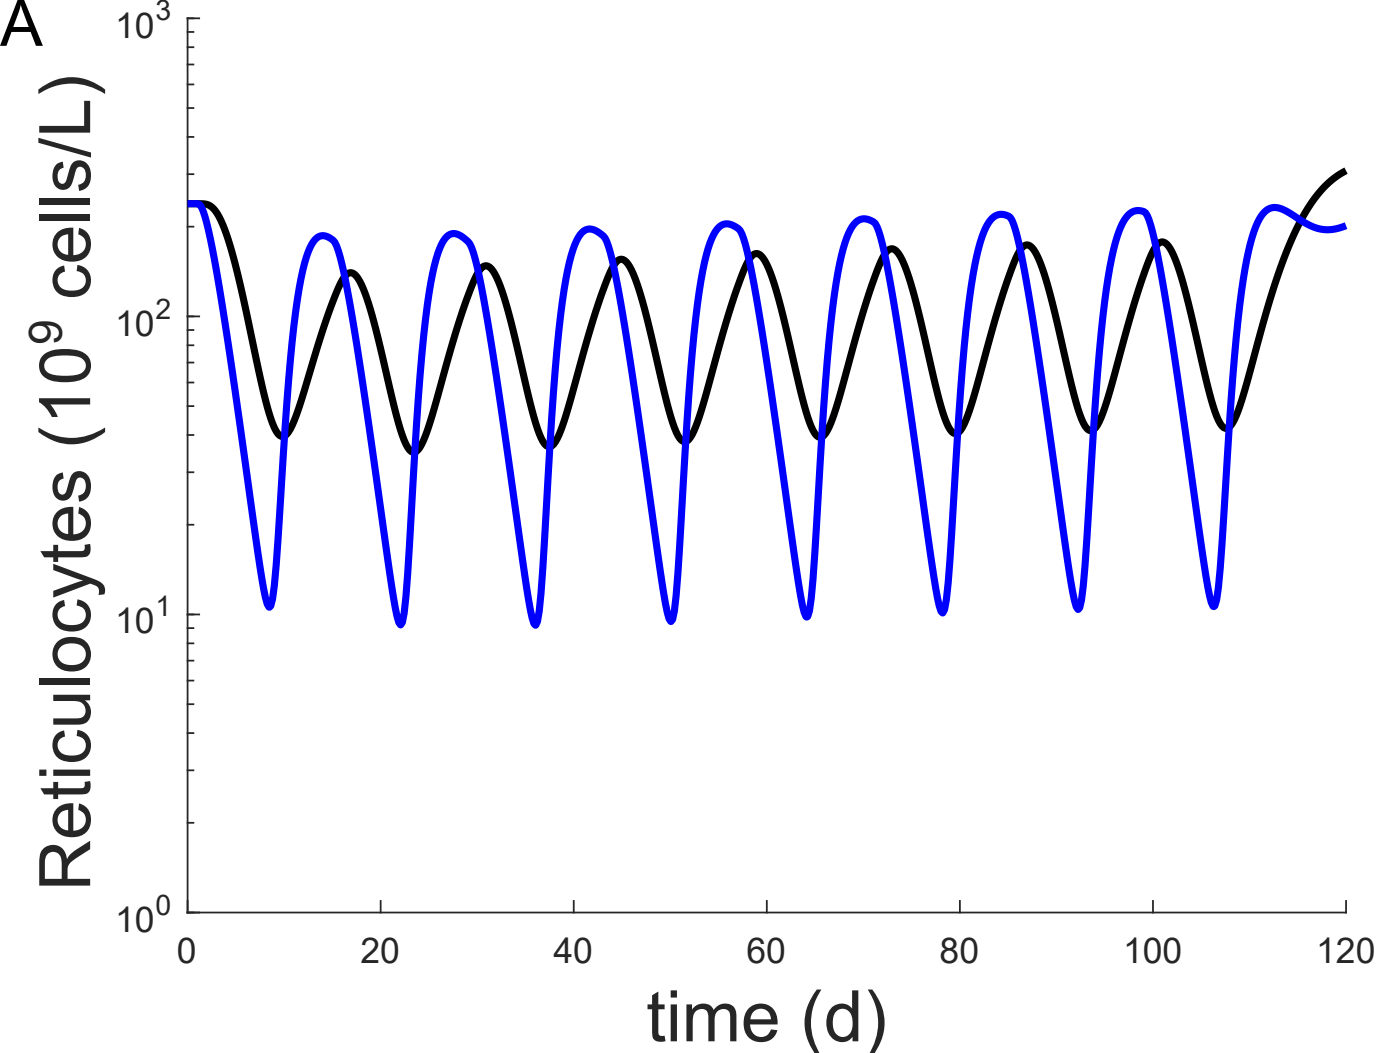

Figure S6. Proliferation in immature transit cells result in relatively large oscillations in reticulocytes and platelets as experimentally observed. Carboplatin induced severe depletion in reticulocytes (panel A) and platelets (panel B), but within each one of the eight cycles strong rebound was observed for both cell populations. Black lines show that these large oscillations could not be explained by a model where MEP (black lines) were the only type of proliferative cells within the reticulocyte and platelet lineages. In our model (blue lines), we hypothesized that also immature transit cells were proliferative, and this resulted in the prediction of relatively large oscillations for circulating reticulocytes and platelets.
